# Regression Analysis

- Sometimes you want to know the magnitude of the effect of one variable on another variable
- Knowing the rate (magnitude) of change in one variable as a result of the other, means that regression can be used to build a predictive model that can be applied to other situations
- It allows you to predict the value/s of the dependent variable for a given value/s of the independent variable

# Correlation and regression analysis

Correlation & regression **CANNOT** be used interchangeably

- The two analyses are based on different assumptions about the nature of the relationship between the two variables examined
- **Regression analysis:** assumes a **cause & effect** relationship. The independent variable is responsible for some of the observed variability in the dependent variable. This cause & effect relationship is assumed to work in only one direction.
  - *E.g., island size can determine species richness of the island, but not vice versa*
- **Correlation analysis:** There is no assumption of cause and effect or dependence of one variable on another (i.e. X does not cause Y to change; X does not affect Y).
- It is only assumed that the two variables are related in some way (i.e. as X changes so does Y but the change in Y is NOT necessarily caused by X).

# Correlation and regression analysis

Correlation & regression **CANNOT** be used interchangeably

# Simple linear regression

- Simple: 2 variables
- Linear: only linear relationships
- Assumes “cause and effect” relationship therefore:
  - Independent variable or **predictor** variable (**X-axis**)
  - Dependent variable or **response/outcome** variable (**Y-axis**)

# Simple linear regression

Regression analysis fits a 'line of best fit' through the XY data and then analyses the parameters that describe the regression line

- Does the regression model describe the relationship between the data well (is it a good fit for the data)?
- Is the slope significantly different from a zero slope?

Line of best fit through the data =  
REGRESSION line

# Regression Analysis

The regression line is expressed by a linear equation that describes the relationship between X and Y (the regression model)

**Two important parameters describe the regression line**

Intercept  $\rightarrow$   $Y_i = \alpha + \beta X_i$   $\leftarrow$  Slope

$Y_i$  -  $i^{\text{th}}$  observation of variable Y (dependent)

$X_i$  -  $i^{\text{th}}$  observation of variable X (independent)

$\alpha$  - **intercept** of the regression line (the value of

$\beta$  - the **slope** of the regression line  
(change in Y per unit change in X)

# Regression Analysis

Two important parameters describe the regression line

$$Y_i = \alpha + \beta X_i$$

**Slope ( $\beta$ )**

The least squares estimate of the slope coefficient ( $\beta$ ) of the true regression line is:

$$\beta = \frac{\sum (x_i - \bar{x})(y_i - \bar{y})}{\sum (x_i - \bar{x})^2} = \frac{S_{xy}}{S_{xx}}$$

Shortcut formulas for the numerator and denominator:

$$S_{xy} = \sum x_i y_i - (\sum x_i)(\sum y_i)/n \quad \text{and} \quad S_{xx} = \sum x_i^2 - (\sum x_i)^2/n$$

# Regression Analysis

Two important parameters describe the regression line

$$Y_i = \alpha + \beta X_i$$

Intercept (points to  $\alpha$ )      Slope (points to  $\beta$ )

## Slope ( $\beta$ )

Indicates the **magnitude** of the effect of X on Y i.e., the rate at which Y changes for every 1 unit increase in X

Can be positive, negative, zero (direction of relationship)

If  $\beta = 1.86$ , then Y increases by 1.86 units for every 1 unit increase in X

If  $\beta = -0.92$ , then Y decreases by 0.92 units for every 1 unit increase in X

# Regression Analysis

Two important parameters describe the regression line

Intercept   $Y_i = \alpha + \beta X_i$   Slope

The diagram shows the regression equation  $Y_i = \alpha + \beta X_i$ . A red circle highlights the intercept  $\alpha$ , with a red arrow labeled "Intercept" pointing to it. A blue circle highlights the slope  $\beta$ , with a blue arrow labeled "Slope" pointing to it.

## Intercept ( $\alpha$ )

The least squares estimate of the intercept ( **$\alpha$** ) of the true regression line is:

$$\hat{\beta}_0 = \bar{y} - \hat{\beta}_1 \bar{x}$$

- **$\hat{\beta}_0$  (Estimated Intercept):** The predicted value of  $y$  when  $x$  is zero. It's where the regression line crosses the vertical axis.
- **$\bar{y}$  (Sample Mean of  $y$ ):** The average of all observed values for the **dependent variable**.
- **$\hat{\beta}_1$  (Estimated Slope):** The amount  $y$  is expected to change for every one-unit increase in  $x$ .
- **$\bar{x}$  (Sample Mean of  $x$ ):** The average of all observed values for the **independent variable**.

# How is a good regression line calculated?

- Most common is Least squares regression
- Goal is to minimize the sum of all the squared deviations between the observed values of  $Y$  and the predicted values by the regression line (i.e., it looks for the smallest variability in the residuals around the line)
- The residual is the vertical distance between the observed value ( $y$ ) and the predicted value ( $\hat{y}$ ), and it is calculated by subtracting  $\hat{y}$  from  $y$
- Residuals and least squares regression video: <https://www.youtube.com/watch?v=VqD-nf1YUks>

# How is a good regression line calculated?

## Calculating residuals:

- Residual = actual  $y$  value – predicted  $y$  value

$$r_i = y_i - \hat{y}_i$$

- Regression line equation...

$$\hat{y}_i = a + bx_i$$

- Residual of an observation...

$$r_i = y_i - \hat{y}_i = y_i - (a + bx_i)$$

# **Testing the significance of a regression line**

# Hypothesis Testing with Regression

Two forms of the general null hypothesis  $H_0: \beta = 0$  can be tested

The slope of the relationship is 0

1.  $H_0: \beta = 0$ ;  $X$  has no effect on  $Y$  i.e.  $Y$  is not dependent on  $X$
2.  $H_0$ :  $X$  and  $Y$  are not linearly related: tests appropriateness of whole regression model (intercept and slope) for describing the relationship between  $X$  &  $Y$

# Hypothesis Testing with Regression

**E.g.** Determine whether the number of eggs produced by female fish is affected by water temperature.

- $H_A$ : number of eggs produced is linearly related to water temperature
- $H_0$ : number of eggs produced, and water temperature are not linearly related
  
- $H_A$ : change in water temperature affects number of eggs produced
- $H_0$ : change in water temperature has no effect on number of eggs produced

# Hypothesis Testing with Regression

## Evaluating the slope of the regression

The slope of the regression can be evaluated with *one sample t-test*

1.  $H_0: \beta = 0$  is evaluated with a *t-test*

Compares the slope of the regression line with a hypothetical slope of 0

Measures how many standard errors the estimated sample slope is away from 0

Evaluates significance of the slope (t-statistic)

$$t = \frac{\beta - 0}{s\beta}$$

Slope of the regression line

$s\beta$

Standard error of the slope

# Hypothesis Testing with Regression

## Evaluating the slope of the regression

**Example:** If we have a slope: of 1.86 and standard error of the slope 0.16

$$t = \frac{\beta - 0}{s_{\beta}}$$
$$\frac{1.86 - 0}{0.16} = \frac{1.86}{0.16}$$

$$t = 11.63$$

$$df = n - 2$$

### 1. Reject the Null Hypothesis ( $H_0$ )

- **Condition:**  $|t_{\text{calculated}}| \geq t_{\text{critical}}$
- **Action:** You **reject**  $H_0$ .
- **Conclusion:** There is a **statistically significant linear relationship** between the independent variable  $x$  and the dependent variable  $y$ .

### 2. Fail to Reject the Null Hypothesis ( $H_0$ )

- **Condition:**  $|t_{\text{calculated}}| < t_{\text{critical}}$
- **Action:** You **fail to reject**  $H_0$ .
- **Conclusion:** There is not enough evidence to conclude a linear relationship exists. Changes in  $x$  do not reliably predict  $y$  in the model.

# Hypothesis Testing with Regression

## Evaluating linear regression

- Linear regression can be evaluated using an **ANOVA** (Analysis of Variance)
- Evaluates significance of the regression model using the *F-statistic*

2.  **$H_0$ :  $X$  and  $Y$  are not linearly related** is evaluated using an **ANOVA**

Calculates the ratio of the variability in the dependent variable that is explained by the regression model to the unexplained variability

Variability in the response variable ( $Y$ ) explained by the regression or due to  $X$

$$F = \frac{\text{Regression Variance}}{\text{Residual Variance}}$$

Unexplained variability in the response variable ( $Y$ ) around the regression line

# Hypothesis Testing with Regression

## Evaluating linear regression

Variability in the response variable ( $Y$ ) explained by the regression or due to  $X$

$$F = \frac{\text{Regression Variance}}{\text{Residual Variance}}$$

Unexplained variability in the response variable ( $Y$ ) around the regression line

Total variation = Explained variation + Unexplained variation

Measured by:

Sum of squares total: SST = Sum of squares regression: SSR + Sum of squares error: SSE

$$\sum (Y - \bar{Y})^2 = \sum (\hat{Y} - \bar{Y})^2 + \sum (Y - \hat{Y})^2$$

- $Y$  = Observed value of  $Y$
- $\bar{Y}$  = Mean value of  $Y$
- $\hat{Y}$  = Predicted value of  $Y$  (regression line)

$$Y = \beta_0 + \beta_1 X + \varepsilon$$

$\varepsilon_i$  (**Error Term**): In the real world, data points rarely fall perfectly on a straight line. This term represents the "noise" or the distance between the actual observed data point and the predicted line.

Total variation

Recall: Variance of  $Y$ :  $s_Y^2 = \frac{\sum_{i=1}^n (Y_i - \bar{Y})^2}{n-1}$

Degrees of freedom

# Hypothesis Testing with Regression

## Evaluating linear regression

### The Setup

Imagine we find that for every hour a student studies, their score goes up by 5 points. Even if they don't study at all, they'd likely get a 40 just by guessing or using prior knowledge.

In this scenario, our equation  $y_i = \beta_0 + \beta_1 x_i + \varepsilon_i$  looks like this:

- $y_i$  (**Exam Score**): The result we want to predict.
- $x_i$  (**Hours Studied**): The input we are measuring.
- $\beta_0 = 40$ : The "baseline" score if hours studied ( $x$ ) is zero.
- $\beta_1 = 5$ : The "boost" per hour of studying.
- $\varepsilon_i$  (**The "Human Factor"**): This accounts for things like how much sleep the student got or how lucky they were with the questions.

# Hypothesis Testing with Regression

## Evaluating linear regression

### The Prediction

If a specific student studies for **8 hours**, the formula predicts their score:

$$\text{Score} = 40 + (5 \times 8) = 80$$

However, if that student actually scores an **83**, the  $\varepsilon_i$  (**error term**) for that student is **+3**. The model predicted 80, but the reality was slightly different.

### Summary Table

| Component                 | Real-World Meaning                  |
|---------------------------|-------------------------------------|
| Intercept ( $\beta_0$ )   | Starting score with zero effort.    |
| Slope ( $\beta_1$ )       | The "payoff" for each hour of work. |
| Error ( $\varepsilon_i$ ) | Individual luck or outside factors. |

# Regression Analysis

- Measure of Explained Variation ~ The measure of **Goodness of Fit**
- It is the **Coefficient of determination ( $r^2$ )**: the % of total variation in  $Y$  that is explained by the regression with  $X$
- Gives an indication of the strength of the association and the explanatory power of the model
  - $r^2 = 0.92$ 
    - 92% of the variability in  $Y$  can be explained by  $X$
    - 8% of the variability in  $Y$  is unexplained

$$r^2 = \frac{\text{Explained Variation}}{\text{Total Variation}} = \frac{SSR}{SST} = \frac{\sum (\hat{Y} - \bar{Y})^2}{\sum (Y - \bar{Y})^2} \Leftrightarrow r^2 = 1 - \frac{SSE}{SST}$$

Model Summary

| Model | R                 | R Square | Adjusted R Square | Std. Error of the Estimate |
|-------|-------------------|----------|-------------------|----------------------------|
| 1     | .961 <sup>a</sup> | .923     | .917              | 3.46541                    |

a. Predictors: (Constant), X

$r^2 = 0.923$ ; 92% of the variability in Y is explained by X

$$r^2 = \frac{\text{Explained Variation}}{\text{Total Variation}} = \frac{SSR}{SST} = \frac{\sum (\hat{Y} - \bar{Y})^2}{\sum (Y - \bar{Y})^2} \Leftrightarrow r^2 = 1 - \frac{SSE}{SST}$$

ANOVA<sup>b</sup>

| Model |            | Sum of Squares | df | Mean Square | F       | Sig.              |
|-------|------------|----------------|----|-------------|---------|-------------------|
| 1     | Regression | 1735.391       | 1  | 1735.391    | 144.507 | .000 <sup>a</sup> |
|       | Residual   | 144.109        | 12 | 12.009      |         |                   |
|       | Total      | 1879.500       | 13 |             |         |                   |

a. Predictors: (Constant), X

b. Dependent Variable: Y

$F = 144.507$ ; calculated by dividing Mean Square of Regression by Mean Square of Residual (Error)

$p = 0.000$ , which should be stated as  $p < 0.0005$   
There is a significant linear relationship between X and Y

# Regression Analysis

Coefficients<sup>a</sup>

| Model |            | Unstandardized Coefficients |            | Standardized Coefficients | t      | Sig. |
|-------|------------|-----------------------------|------------|---------------------------|--------|------|
|       |            | B                           | Std. Error | Beta                      |        |      |
| 1     | (Constant) | 3.217                       | 1.781      |                           | 1.807  | .096 |
|       | X          | 1.862                       | .155       | .961                      | 12.021 | .000 |

a. Dependent Variable: Y

y-intercept = 3.217  
slope = 1.862

$t$  of the slope = 12.021, with  $p < 0.0005$

Statistical conclusion: slope of relationship between X and Y is significantly different from 0

Biological conclusion: X has a significant effect on Y; Y increases at a rate of 1.86 for each 1-unit increase in X

$$t = \frac{\beta - 0}{s_{\beta}}$$

# Regression Analysis

## Predicting values of Y from the regression line

- The equation for the regression line can be used to predict values of Y, based on values of X, intercept and slope
- **Example:** In a study comparing species richness with frequency of burning
  - slope ( $\beta$ )= 1.86
  - intercept = 3.22
  - $X_i = 4$
- What is the expected species richness in a plot that was last burned 4 years ago?

$$\hat{y}_i = a + bx_i$$

$$Y_i = 3.217 + 1.862 (4) = 3.217 + 7.44 = 10.66$$

- Should only use when the regression model is **significant**, and you have a **good  $R^2$**  – independent variable (X) explains a large proportion of the variability in the dependent (Y)

# Assumptions of Linear Regression

## 1. The relationship between X and Y is linear

- Check with a scatterplot
- If visually you detect that your data are not linear then transform or
- Use non-linear or polynomial regression analysis

# Assumptions of Linear Regression

## 2. Residuals of the dependent variable are normally distributed

- Check with a **histogram of the residuals** AND
- Use Shapiro-Wilk test or Kolmogorov-Smirnov test for normality
- Shapiro–Wilk test - for small sample sizes ( $n < 50$ ), but can handle larger sample sizes
- Kolmogorov–Smirnov test is used for  $n \geq 50$
- Or a **Q-Q Plot of the residuals**

# Assumptions of Linear Regression

## 3. Variance of residuals is equal across range of X

- Use a Levene's test (F-ratio) on the residuals
  - If  $p > 0.05$  then assumption of equal variances is satisfied
- Can also plot the residuals in place of the dependent variable
  - If there is homogeneity of variance, then the residuals will be evenly distributed across the x axis and centred on a value of 0

# Assumptions of Linear Regression

- 4. **Samples are independent of each other (values in one variable are not influenced by other values in the dataset)**
- 5. **No/little measurement error of  $X$**
