## **Binary exploitation and reverse engineering**

Donn Morrison

Department of Computer Science

# Outline

Native binaries

Reverse engineering  
Tools

# Introduction to binary exploitation

- C and C++ programs (memory management is hard)
- Used for systems programming, so use is widespread
- IoT devices, operating systems, etc...
- Rust aims to protect the programmer from a lot of common pitfalls

We focus on memory corruption issues and unsafe libc function calls.

# ELF file format

- Executable and linkable format
- Standard executable format for Unix-like OSes
- Information in ELF can reveal some general security protections
  - Relocation read-only (RELRO)
  - Stack canary
  - NX stack
  - Position independent executable (PIE)
  - FORTIFY\_SOURCE

[https://upload.wikimedia.org/wikipedia/commons/e/e4/ELF\\_Executable\\_and\\_Linkable\\_Format\\_diagram\\_by\\_Ange\\_Albertini.png](https://upload.wikimedia.org/wikipedia/commons/e/e4/ELF_Executable_and_Linkable_Format_diagram_by_Ange_Albertini.png)

<https://developers.redhat.com/articles/2023/07/04/developers-guide-secure-coding-fortifysource>

# Buffer overflow

- Stack-based
- Heap-based

```
// bo.c buffer overflow example
int main()
{
    char buff[32];
    gets(buff);
    puts(buff);
}
```

```
$ gcc -o /tmp/bo /tmp/bo.c -no-pie
$ python -c "print('A'*40)" | /tmp/bo
AAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAA
Segmentation fault (core dumped)
```

## Stack (64-bit)

```
+-----+
| (high mem) |
| ... |
+-----+
| return addr |
+-----+
| rbp |
+-----+
| buff[24-32] |
+-----+
| buff[16-23] |
+-----+
| buff[8-15] |
+-----+
| buff[0-7] |
+-----+
| ... |
+-----+
```

# Buffer overflow cont.

```
$ checksec /tmp/bo
[*] '/tmp/bo'
  Arch:      amd64-64-little
  RELRO:     Partial RELRO
  Stack:     No canary found
  NX:        NX enabled
  PIE:       No PIE (0x400000)
```

## Mitigations

- Address space layout randomisation (ASLR)
- Stack canary detects stack smashing (Read me!  
<https://www.sans.org/blog/stack-canaries-gingerly-sidestepping-the-cage/>)
- Non-executable (NX) stack/heap
- Position independent executable (PIE)

# A word about shellcode

```

8049000:    31 c9                xor    %ecx,%ecx
8049002:    6a 0b                push   $0xb
8049004:    58                   pop    %eax
8049005:    51                   push   %ecx
8049006:    68 2f 2f 73 68       push   $0x68732f2f // "//sh"
804900b:    68 2f 62 69 6e       push   $0x6e69622f // "/bin"
8049010:    89 e3                mov    %esp,%ebx
8049012:    cd 80                int    $0x80

```

Becomes:

```
char [] shellcode = "\x31\xc9\x6a\x0b\x58\x51\x68\x2f\x2f\x73\x68\x68\x2f\x62\x69\x6e\x89\xe3\xcd\x80";
```

- Shellcode is user input supplied in the context of an exploit
- Specially crafted instructions to execute code, typically a shell
- Non-executable stack/heap greatly reduces ability to run shellcode
- More on how we get around this later...

<https://www.exploit-db.com/shellcodes/46809>

# Use-after-free/dangling pointer

```
// Fedora 20 x64: gcc ./uaf.c
struct unicorn_counter { int num; };

int main() {
    struct unicorn_counter* p_unicorn_counter;
    int* run_calc = malloc(sizeof(int));
    *run_calc = 0;
    free(run_calc);
    p_unicorn_counter = malloc(sizeof(struct unicorn_counter));
    p_unicorn_counter->num = 42;
    if (*run_calc) execl("/bin/gnome-calculator", 0);
}

// <-- The free
// <-- The use
```

# Use-after-free/dangling pointer cont.

Also possible on the stack if a pointer points to a stack location that goes out of scope

```
int main()
{
    int *pointer = NULL;

    if (1) {
        int var = 42;
        pointer = &var; // pointer gets stack address of var
    } // var falls out of scope

    pointer; // <-- dangling
}
```

# Format string vulnerability

- User input passed directly to dangerous functions
- Family of `*printf` string formatting functions
- Ability to read and write from memory
- `https://en.wikipedia.org/wiki/Uncontrolled_format_string`

```
// fs.c format string example
#include <stdio.h>
int main()
{
    char buff[32];
    fgets(buff, 32, stdin);
    printf(buff);
}
```

Try it out, pass `%10$p` as `stdin`, and we get the next 10

# Format string vulnerability cont.

From man 3 printf:

- p The void \* pointer argument is printed in hexadecimal (as if by %x or %lx).
- n The number of characters written so far is stored into the integer pointed to by the corresponding argument. That argument shall be an int \*, or variant whose size matches the (optionally) supplied integer length modifier. No argument is converted. (This specifier is not supported by the bionic C library.) The behavior is undefined if the conversion specification includes any flags, a field width, or a precision.

[https://stackoverflow.com/questions/7459630/  
how-can-a-format-string-vulnerability-be-exploited#  
7459758](https://stackoverflow.com/questions/7459630/how-can-a-format-string-vulnerability-be-exploited#7459758)

# Many, many more possible memory bugs

See <https://googleprojectzero.blogspot.com/2015/06/what-is-good-memory-corruption.html> for some good examples with popping calculators.

# Return-oriented programming

- Non-executable stack made things difficult
- We can inject our own shellcode but cannot run it
- But...we can jump to arbitrary locations in .text (program code) of the running program, or in any shared libraries loaded into process memory
- We can search for *gadgets* of instructions ending in the `ret` instruction

```
$ gcc -o rop rop.c -no-pie
$ ROPgadget --binary rop
...
0x00000000000001013 : add esp, 8 ; ret
0x00000000000001012 : add rsp, 8 ; ret
0x00000000000011e1 : call qword ptr [r15 + rbx*8]
0x00000000000011e2 : call qword ptr [rdi + rbx*8]
0x0000000000001010 : call rax
0x00000000000010f7 : cmc ; add byte ptr cs:[rax], al ; test rax, rax ; je 0x1111 ; jmp rax
0x00000000000011e4 : fisttp word ptr [rax - 0x7d] ; ret
0x000000000000100e : je 0x1014 ; call rax
...
```

## Return-oriented programming cont.

- Build up some “shellcode” using ROP chains
- Each time *ret* called, we pop the top of the stack off into the instruction pointer
- CPU continues executing at that location
- So our buffer overflow should overwrite the stack with a chain of the addresses of gadgets we want to execute in order

More in ROP:

- LiveOverflow ROP differently explaining part 1  
<https://www.youtube.com/watch?v=8Dcj19KGKWM>
- LiveOverflow Return-oriented programming tutorial  
<https://www.youtube.com/watch?v=zaQVNM3or7k>

# Outline

Native binaries

Reverse engineering  
Tools

# Introduction

The process of understanding how a piece of software works (usually at a very low level)

— Reverse engineering (RE) contexts

- Recreating outdated/incompatible software or protocols (no available source code)
- Software freedom
- Understanding malicious code
- Exploiting vulnerabilities
- Circumvent copy protection, DRM
- Curiosity
- Research (information security)

# Examples

- Non-IBM PC-BIOS (launched the IBM-PC compatible industry)
- Samba <https://www.samba.org/> (Windows file share)
- Wine (Windows API)
- OpenOffice/LibreOffice (MS doc formats)
- ReactOS (binary compatibility with Windows NT)

[https://en.wikipedia.org/wiki/Reverse\\_engineering#Reverse\\_engineering\\_of\\_software](https://en.wikipedia.org/wiki/Reverse_engineering#Reverse_engineering_of_software)

# Techniques

- Analysis
  - Observing information exchange
  - Bus analysers, packet sniffers
  - JTAG for embedded systems
  - Low-level debuggers (SoftICE for debugging MS Windows)
- Binary disassembly
  - Study of machine code
  - Can be slow and tedious
- Decompilation
  - Use a tool to try to recreate the original source code (varying degrees of success)

# Tools

- Disassembler (objdump, radare2, Ghidra, IDA) - static analysis
- Debugger (gdb (with peda), OllyDbg, ...) - dynamic analysis
- Hex, resource editors
- Firmware unpackers, e.g., binwalk

# Disassembler - objdump

display information from object files

```
$ objdump -d /tmp/fork/a.out -M intel
```

```
/tmp/fork/a.out:      file format elf64-x86-64
```

Disassembly of section .init:

# Disassembler - radare2

Advanced commandline hexadecimal editor, disassembler and debugger

The screenshot shows the radare2 disassembler interface. The title bar indicates the user is 'donn@donn-ThinkPad-X260' and the file path is '~/NTNU/Teaching/TDAT3020-Sikkerhet i programvare og nettverk'. The menu bar includes 'File', 'Edit', 'View', 'Search', 'Terminal', and 'Help'. The command line shows the user is at address 0x0000063a, viewing the 'main' function, with 3 nodes, 3 edges, and a zoom of 100%. The assembly code is displayed in a dark theme with syntax highlighting. The code for the 'main' function is shown, including a call to 'sym.imp.fork' and a jump to '0x642'. The code is as follows:

```
[0x63a] ;[ga]
;-- main:
(fcn) main 18
main ();
; var int local_4h @ rbp-0x4
; DATA XREF from 0x0000054d (entry0)
push rbp
mov rbp, rsp
sub rsp, 0x10

0x642 ;[gc]
; JMP XREF from 0x0000064a (main + 16)
call sym.imp.fork:[gb]
mov dword [rbp - 4], eax
jmp 0x642:[gc]
```

# Disassembler - radare2

```

# Disassembler - IDA Pro

Multiarchitecture disassembler, debugger, decompiler

# Disassembler/decompiler - Ghidra

- Multiarchitecture disassembler, decompiler
- Developed by NSA's Research Directorate
- Open-sourced early 2019

# Demos

- GNU debugger `gdb` with `peda`
  - Basic ROP exploit example - `rop.c` - `ROPgadget/one_gadget/radare2 /R`
- Reverse engineering an IoT binary
  - `binwalk`
  - `strings`
  - `Ghidra`

# Pwning a router Pwn2own 2020

This short series documents recon, reverse engineering, and exploit writing to get a remote root shell on a router.
